

PRACTICAL 2

Practical2(1)

Problem Phase

This problem is about **searching for a target licence plate in an array** using two methods: iterative linear search and recursive linear search.

Solution

The **iterative method** checks each element one by one using a loop, while the **recursive method** checks one element and calls itself for the next element until the target is found or the array ends. If the target is found, its position is displayed; otherwise, it shows that the licence plate was not found.

Practical2(2)

Problem Phase

This problem is about searching for a target book code in a sorted array using iterative and recursive binary search.

Solution

The iterative binary search repeatedly divides the search range into half using a loop. The recursive binary search also divides the range into half but calls the function again for the required half. If the middle element matches the target, its position is returned; otherwise, the search continues until the element is found or the range becomes empty.
