PRACTICAL 9:

Practical9(1)

Problem Phase:

Implement Depth First Search (DFS) and Breadth First Search (BFS) on a graph representing city buildings connected by roads. Start from a given building and print the visiting order for both strategies.

Solution:

DFS uses a stack to explore deeply before backtracking, while BFS uses a queue to visit neighboring buildings level by level. Therefore, DFS explores depth-wise, whereas BFS explores breadth-wise from the starting building.
